ABSTRACT

Hyperplasia of the PTG underlies the secondary hyperparathyroidism (SHPT) observed in CKD, but the mechanism underlying this hyperplasia is incompletely understood. Because aberrant cyclooxygenase 2 (COX2) expression promotes epithelial cell proliferation, we examined the effects of COX2 on the parathyroid gland in uremia. In patients with ESRD who underwent parathyroidectomy, clusters of cells within the parathyroid glands had increased COX2 expression. Some COX2-positive cells exhibited two nuclei, consistent with proliferation. Furthermore, nearly 78% of COX2-positive cells expressed proliferating cell nuclear antigen (PCNA). In the 5/6-nephrectomy rat model, rats fed a high-phosphate diet had significantly higher serum PTH levels and larger parathyroid glands than sham-operated rats. Compared with controls, the parathyroid glands of uremic rats exhibited more PCNA-positive cells and greater COX2 expression in the chief cells. Treatment with COX2 inhibitor celecoxib significantly reduced PCNA expression, attenuated serum PTH levels, and reduced the size of the glands. In conclusion, COX2 promotes the pathogenesis of hyperparathyroidism in ESRD, suggesting that inhibiting the COX2 pathway could be a potential therapeutic target.

Secondary hyperparathyroidism (SHPT) is one of the most common abnormalities of mineral metabolism in patients with chronic kidney disease (CKD), characterized by hyperplasia of the parathyroid gland (PTG).1 It is well documented that increased parathyroid hormone (PTH) contributes to bone disorders and cardiovascular complications of ESRD patients and is associated with the morbidity and mortality of this population.2,3 Strong evidence indicates that PTG hyperplasia is positively linked to the circulating levels of PTH, and the size of the PTG is associated with the controllability of parathyroid function in CKD patients.4,5 The mechanism underlying PTG hyperplasia is incompletely defined.

Under normal conditions, the turnover rate of the PTG is very low, and mitoses are seldom observed.14 However, under certain pathologic conditions such as CKD, hyperphosphatemia, and vitamin D deficiency, increased proliferation of the PTG can be detected.7,8 In CKD patients, the PTG shows diffuse and polyclonal proliferation at early stages of SHPT. With progression of the disease, the PTG can transform with monoclonal and aggressive proliferation.9–11 It is well accepted that PTG hyperplasia is associated with reduced 1,25-vitamin
D synthesis from the kidney and downregulation of the vitamin D receptor (VDR)\textsuperscript{12} and calcium-sensing receptor in the PTG.\textsuperscript{13,14} In the hyperparathyroidism tissue, the expression of the cyclin-dependent kinase inhibitors p21 and p27 is depressed in a VDR-dependent manner.\textsuperscript{15,16} Recently, EGF receptor (EGFR) activation by TGF-\(\beta\) has also been suggested to play an important role in the growth of the PTG and the downregulation of VDR, which may be associated with vitamin D resistance in advanced SHPT in ESRD.\textsuperscript{17} EGFR activation may lead to activation of cyclin D1, an important contributor to parathyroid hyperplasia in humans.\textsuperscript{18}

Cyclooxygenase (COX) catalyzes the rate-limiting step in the synthesis of prostaglandins (PGs) from arachidonic acid (AA). Two isoforms have been identified, COX1 and COX2. COX1 is constitutively expressed, whereas COX2 is induced by various mitogenic and inflammatory stimuli.\textsuperscript{19–21} Multiple lines of evidence suggest that COX2 plays a significant role in carcinogenesis by promoting cell proliferation, inhibiting apoptosis, and stimulating angiogenesis.\textsuperscript{20,22} Nonselective COX inhibitors and selective COX2 inhibitors have been shown to have chemopreventive and therapeutic effects on many types of tumors.\textsuperscript{23}

COX-derived PGs were reported in bovine PTGs.\textsuperscript{24} COX1 and COX2 expression has been observed via immunohistochemistry in the oxyphil cells of the PTG from patients.\textsuperscript{25} PGE\(_2\), a bioactive product of COX, was reported to increase PTH production.\textsuperscript{26,27} These studies are consistent with a potential role of COX-derived PGs in the pathogenesis of SHPT and led us to propose that COX2 may be involved in the pathogenesis of parathyroid hyperplasia.

**RESULTS**

**COX2 is Expressed in the Hyperplastic PTG from Hemodialysis Patients and Is Associated with Cell Proliferation**

Among 39 PTGs obtained from hemodialysis patients, 12 glands showed diffuse hyperplasia and 27 glands exhibited nodular hyperplasia. Chief and oxyphil cells were present in the hyperplastic regions. Using an immunohistochemistry method, COX2 immunoprotein was detected in clusters of cells within the hyperplasia PTGs (Figure 1A), whereas COX1 expression was barely detectable (data not shown). Interestingly, the distribution of COX2 positivity seems to be influenced by the degree of tissue hyperplasia. In the diffuse hyperplastic parathyroid, the distribution of COX2-positive cells was diffuse and the intensity was relatively uniform (Figure 1, A1 and A4), whereas in the nodular hyperplastic parathyroid, COX2-positive cells were mainly distributed in the periphery of the nodule and the cells within the nodule showed weak COX2 immunoreactivity (Figure 1, A2, A3, A5, and A6). Immunoblot analysis further indicated that the levels of COX2 expression in the diffuse hyperplastic parathyroid tissues were higher than those in nodular hyperplastic tissues (Figure 1B).

To examine whether COX2 expression is associated with cell proliferation and to determine the cell type that expresses COX2, we performed immunohistochemistry and hematoxylin and eosin (H&E) staining in serial sections of PTGs. Cell proliferation was marked by PCNA expression as previously reported.\textsuperscript{7} COX2 and PCNA expression were observed in eosinophilic (oxyphil) cells and chief cells of human hyperplastic

![Figure 1](image-url). COX2 is expressed in the hyperplastic PTGs from hemodialysis patients. PTGs (Figure 2). Nearly 78% of COX2-positive cells also expressed PCNA (Figure 3, B and C), supporting that COX2 overexpression was associated with cell proliferation in the uremic parathyroids. Expression of COX2 in proliferating cells was further supported by the immunohistochemistry showing COX2 expression in cells with two nuclei (Figure 3A).

COX2 Inhibitor Suppresses the Hyperplasia of Parathyroid in the 5/6-Nephrectomized Rats Fed with a High-Phosphate Diet

A 5/6-nephrectomy (Nx) rat fed with high dietary phosphate is a widely used animal model of human SHPT and is characterized by diffuse proliferation of chief cells in the PTG. To examine the role of COX2 in hyperplasia of the parathyroid, we treated the rats with the COX2 inhibitor celecoxib 1 month after Nx for subsequent 2 months. Table 1 illustrates the body weights and serum chemistries in Nx and sham-operated rats fed with or without celecoxib. As expected, body weight gain was retarded in uremic rats compared with the sham-operated rats. There was no significant difference in serum calcium levels among three groups of animals. Serum creatinine, blood urea nitrogen (BUN), and serum phosphorus increased significantly in the uremic animals fed with the high-phosphate diet. Serum PTH levels and the size of the PTG were also significantly increased in the Nx rats fed with a high-phosphate diet (Figure 5).

Consistent with the studies in uremic patients, the uremic rats on a high-phosphate diet demonstrated increased COX2 expression (Figure 6A) and PGE2 biosynthesis in the PTG (Nx: 208.76 ± 31.28 versus sham: 159.01 ± 5.20 pg/mg protein, P < 0.05) but not in serum (Figure 4). The COX2 protein and mRNA levels in the uremic parathyroid were 2.5-fold and 39-fold compared with normal rats, respectively (P < 0.001) (Figure 6, B and C). The increased PGE2 production was abolished by the COX2 inhibitor celecoxib (164.82 ± 3.10 pg/mg protein) (Figure 4B). Treatment with celecoxib for 2 months also significantly attenuated serum PTH levels (Table 1) and reduced the maximal PTG area to 50% of those without celecoxib (Figure 5). Celecoxib treatment had no significant effect on serum creatinine, BUN, and phosphorus levels.

Immunohistochemistry analysis demonstrated a few PCNA-positive cells in the PTGs of sham-operated rats. A high-phosphate diet led to a marked increase in PCNA-positive cells and COX2-positive cells in uremic PTGs compared
with those in controls. The COX2 inhibitor celecoxib not only reduced PGE2 production but also significantly reduced PCNA-positive staining in PTGs (Figure 6A). Immunoblot and real-time PCR analysis (Figure 6, B and C) further supported the effect of celecoxib on PCNA expression. In uremic rats fed with a high-phosphate diet, the protein and mRNA levels of PCNA in parathyroid tissues markedly increased by 2.8-fold and 25-fold compared with those of control rats \((P < 0.001)\). Administration of COX2 inhibitor significantly decreased the excessive protein and gene expression of PCNA by 22\% \((P < 0.05)\) and 56\% \((P < 0.001)\) but had no effects on COX2 expression. In contrast, the COX1 expression in the PTG was very little and there was no significant difference between uremic and normal rats. Therefore, these results strongly suggest that COX2- but not COX1-derived PG plays an important role in the pathogenesis of uremic proliferation of PTGs.

**DISCUSSION**

The mechanism by which hyperparathyroidism is developed in uremic patients is incompletely defined. Phosphate retention, impaired vitamin D metabolism, and the downregulation of the calcium-sensing receptor have been demonstrated to be involved in the pathogenesis of SHPT in CKD patients\(^{7,13,14}\). The study presented here suggests that COX2 also plays an important role in parathyroid hyperplasia in patients with ESRD and participates in the pathogenesis of hyperparathyroidism in these patients. The data presented here show that COX2 expression was markedly increased in uremic animals compared with normal rats.

increased in the PTGs of uremic patients and rats, COX2 expression was associated with cell proliferation, and COX2 inhibitor significantly attenuated parathyroid proliferation and reduced PTH release in the rat model of uremic hyperparathyroidism.

In early 1980s, the cells from PTGs were reported to produce various PGs that were associated with CAMP accumulation and PTH release. Later studies detected COX2 expression in human PTGs, primarily in the oxyphil cells. The study presented here demonstrates that the PTGs of the patients with severe SHPT expressed large amount of COX2. The increased COX2 was localized to oxyphil and chief cells by immunohistochemistry. Elevated COX2 expression was also observed in
To further examine the role of COX2 in the proliferation of parathyroid cells in SHPT, we generated an animal model by 5/6-Nx plus a high-phosphate diet. Immunohistochemical and immunoblot studies revealed that COX2 was markedly induced in the PTGs of the rats with decreased renal mass that were fed a high-phosphate diet. To determine whether increased COX2 expression contributes to increased proliferation of the PTG and increased PTH release, we treated those rats with the COX2 inhibitor celecoxib at the dosage of 100 mg/kg per day, which has been shown to efficiently inhibit COX2 activity and reduce cell proliferation in animal models. Two-month celecoxib treatment dramatically suppressed the increase in maximal PTG area and PCNA expression in the parathyroid tissues, accompanied by reduced serum PTH levels. Celecoxib did not alter renal function or calcium-phosphate levels in uremic rats. Previous studies reported that chronic administration of a selective COX2 inhibitor significantly decreased proteinuria and attenuated development of glomerular sclerosis in rats with reduced renal mass. However, in our study, celecoxib, administered 1 month after Nx, did not significantly improve renal function in the uremic rats with SHPT. Delayed celecoxib treatment after Nx may contribute to the less-protective effect on renal function. It appears that the suppressive effects of the COX2 inhibitor on the parathyroid hyperplasia in uremia is not due to its effect on improving renal function but rather comes from its direct effect on the hyperplastic PTG. Our immunoblot showed that the levels of COX2 expression in the diffuse hyperplastic parathyroid tissues were higher compared with nodular hyperplastic tissues. This may, at least in part, reflect relatively less COX2-positive cells in nodular tissues as shown in our immunohistochemistry studies. Whether COX2 expression levels differ at the cellular level between nodular and diffuse tissues is not clear. Nevertheless, colocalization of COX2 and PCNA in nodular and diffuse hyperplastic parathyroid tissues supports an association of COX2 expression and cell proliferation. Whether COX2-derived prostanoids play a more important role in polyclonal than monoclonal parathyroid hyperplasia remains to be investigated.

COX converts AA to PGH₂, which is subsequently metabolized to multiple bioactive PGs, including PGE₂, PGI₂, PGD₂, PGA₂, and thromboxane A₂. PGE₂ has been demonstrated to stimulate many cellular processes such as proliferation, angiogenesis, and invasion while inhibiting the immune response and apoptosis. The antitumor effects of nonsteroidal anti-inflammatory drugs or COX2 inhibitors are associated with marked reductions in tumor PGE₂ levels. PGE₂ exerts its cellular effects by binding to four distinct E-prostanoid receptors (EP1 to EP4) that belong to the family of seven transmembrane G-protein-coupled receptors. Previous data show that parathyroid tissue and parathyroid cells per se produce various PGs. PGE₂ stimulates cAMP accumulation and PTH release. However, the downstream mechanism by which COX2 mediates parathyroid hyperplasia remains to be determined.

The mechanism by which COX2 is induced in hyperparathyroidism is also unclear. Hypocalcemia, hyperphosphatemia, and vitamin D deficiency have been documented to be critical contributors to the hyperplastic parathyroid growth in CKD. The study presented here showed that high-phosphate diet induced an overexpression of COX2 in hyperplastic PTGs and increased the release of PGE₂ in uremic rats. Recent works have demonstrated a crosstalk between the COX2 and the EGFR, TGF-β, endothelin-1, and other cytokines in cancer research. Coincidentally, these potent growth promoters were also found to be markedly enhanced in the parathyroid and were identified as the main cause of parathyroid hyperplasia in experimental CKD. In any event, further in vitro and in vivo studies will be required before the significance of the COX2 function in the control of the parathyroid response to traditional and novel risk factors of hyperplasia can be established.

In conclusion, we have demonstrated a new direct relationship between COX2 overexpression and parathyroid hyperplasia from hemodialysis patients and high-phosphate induced Nx-SHPT rats. COX2 inhibition ameliorated SHPT and the parathyroid cell growth in experimental rats, independent of renal function. These results suggest that the COX2 pathway may be a potential therapeutic target for SHPT in CKD patients.

**CONCISE METHODS**

**Human Parathyroid Tissue Preparations**
Parathyroid tissues were obtained at the time of parathyroidectomy surgery from 12 maintenance hemodialysis patients (four men and eight women, mean age 49.7 ± 8.0 years, mean duration of hemodialysis therapy 8.8 ± 1.6 years) in our hospital between the years 2005 and 2008 with approval of the Ethics Committee on Human Research at Huashan Hospital, Fudan University, Shanghai, People’s Republic of China. All of the patients had advanced SHPT that was resistant to therapy. Delayed celecoxib treatment after Nx may contribute to the less-protective effect on renal function. It appears that the suppressive effects of the COX2 inhibitor on the parathyroid hyperplasia in uremia is not due to its effect on improving renal function but rather comes from its direct effect on the hyperplastic PTG. Our immunoblot showed that the levels of COX2 expression in the diffuse hyperplastic parathyroid tissues were higher compared with nodular hyperplastic tissues. This may, at least in part, reflect relatively less COX2-positive cells in nodular tissues as shown in our immunohistochemistry studies. Whether COX2 expression levels differ at the cellular level between nodular and diffuse tissues is not clear. Nevertheless, colocalization of COX2 and PCNA in nodular and diffuse hyperplastic parathyroid tissues supports an association of COX2 expression and cell proliferation. Whether COX2-derived prostanoids play a more important role in polyclonal than monoclonal parathyroid hyperplasia remains to be investigated.

COX2 inhibition ameliorated SHPT and the parathyroid cell growth in experimental rats, independent of renal function. These results suggest that the COX2 pathway may be a potential therapeutic target for SHPT in CKD patients.

**In Vivo Experiments in Rats**
The experimental protocol was approved by the Animal Study Committee at Huashan Hospital, Fudan University. 5/6-Nx was performed on 200- to 250-g male Sprague–Dawley rats in a two-step procedure as previously reported. A high-phosphate (1.2%) rodent chow was administered daily via gavage to the SHPT rats. Delayed celecoxib treatment after Nx may contribute to the less-protective effect on renal function. It appears that the suppressive effects of the COX2 inhibitor on the parathyroid hyperplasia in uremia is not due to its effect on improving renal function but rather comes from its direct effect on the hyperplastic PTG. Our immunoblot showed that the levels of COX2 expression in the diffuse hyperplastic parathyroid tissues were higher compared with nodular hyperplastic tissues. This may, at least in part, reflect relatively less COX2-positive cells in nodular tissues as shown in our immunohistochemistry studies. eny of Science. These chows contain identical calcium (1.2%), vitamin D (750 IU/kg), carbohydrate, lipid, and protein contents.

Two months after the treatment, the rats were sacrificed and blood samples were obtained for creatinine, BUN, calcium, phosphorus, intact PTH, and PGE2 measurements. The PTGs were immediately removed using microdissection equipment and prepared for histologic, protein, and mRNA analysis following the protocols described above. For ELISA analysis of PGE2 concentration, part of the parathyroid tissues were homogenized (in ice) in the buffer, which contained 0.1 M phosphate and 10 μM indomethacin at a pH of 7.4. The resultant homogenate was centrifuged for 30 minutes at 4000 rpm at 4°C. The supernatant was aspirated into polypropylene test tubes and stored at −70°C.

Laboratory Measurements
Serum creatinine, BUN, calcium, and phosphorus were determined by an autoanalyzer (Hitachi 7170, Japan). Serum intact PTH was measured by an ELISA kit special for rats (R&D Systems). The amount of PGE2 in serum and parathyroid tissue homogenate was detected using an ELISA kit from R&D Systems.

Histologic Studies
Paraffin-embedded PTG tissue from each hemodialysis patients was cut in multiple consecutive sections for H&E staining and immunohistochemistry. Immunohistochemistry was also performed on paraffin-embedded parathyroid tissue from rats. Sections (4 μm thick) were cut and blocked with 10% horse serum/PBS for 30 minutes at room temperature. The sections were then incubated with the following primary antibodies: (1) anti-COX2 polyclonal antibody (1:100 dilution; Cayman Chemical), (2) anti-COX1 polyclonal antibody (1:100 dilution; Cayman Chemical), and (3) anti-PCNA rabbit polyclonal antibody (1:100 dilution; Santa Cruz Biotechnology, Inc.). After 60 minutes of incubation, the sections were washed and incubated with biotinylated anti-IgG secondary antibody (Jackson Immunoresearch Laboratories, West Grove, PA) for 60 minutes. Signals were visualized with a VECTA STAIN Elite ABC standard kit (Vector Laboratories) and a diaminobenzidine substrate kit (Vector Laboratories). Human hyperplastic PTG specimens were also double-stained with anti-COX2 antibody and anti-PCNA antibody. COX2 was detected with Texas-red-conjugated streptavidin (AK Substrate Kit; Vector). COX2-positive cells, PCNA-positive cells, and co-positive cells were counted per microscope field with the PTG sections completely filling the microscope field. For each patient, five microscope fields were counted and the mean was used for analysis.

Assessment of the Size of the Rat PTG
Serial sections of the paraffin-embedded rat PTGs were cut (4 μm) and stained with H&E. The maximal two-dimensional area of the right or left PTG was determined from at least ten serial sections according to the method described by Nagano et al.57 The sections were examined under a light microscope (Olympus CX40) connected to a computer. A digitizer tablet carefully traced the outside edge of the PTG, and the area inside of the circle was calculated by an image analysis system (Image J). The area of each section was the average of nine measurements by three different investigators (three measurements by each investigator).

Immunoblot
Freshly removed human PTG tissue and microdissected rat PTG tissue free of thyroid tissue were homogenized and extracted in lysis buffer containing 150 mM NaCl, 100 mM Tris-buffered saline (pH 8.0), 1% Tween 20, 50 mM diethylthiocarbamate, 1 mM EDTA, 1 mM phenylmethylsulfonyl fluoride, 10 μg/ml leupeptin, 10 μg/ml aprotinin, 10 μg/ml trypsin inhibitor, and 10 μg/ml pepstatin. Protein concentration was determined using a bicinchoninic acid protein assay (Sigma). Twenty micrograms of protein extract were separated on a 10% SDS-PAGE gel. Protein was transferred to a polyvinylidene difluoride membrane at 22 V overnight at 4°C. The membrane was washed three times with Tris-buffered saline-Tween (50 mM Tris, 150 mM NaCl, and 0.05% Tween 20) and then incubated in blocking buffer (150 mM NaCl, 50 mM Tris, 0.05% Tween 20, and 5% Carnation nonfat dry milk [pH 7.5]) for 1 hour at room temperature. The membrane then was incubated with antibodies (1:200) raised against PCNA, COX2, and COX1 (Cayman Chemical) overnight at 4°C. After three washes, the membrane was incubated with a horseradish-peroxidase-conjugated secondary antibody (1:10,000; Jackson Immunoresearch Laboratories) for 1 hour at room temperature followed by three 15-minute washings. Antibody labeling was visualized by electrochemiluminescence (Amersham Biosciences, England, United Kingdom).

Isolation of Total RNA and Real-Time PCR
Total RNA was extracted from microdissected rat parathyroid tissue using Trizol reagent (Invitrogen, Carlsbad, CA) and then treated with DNase (Takara Bio Inc, Otsu, Shiga, Japan) according to the manufacturer’s protocol. Reverse transcription was carried out using the SuperScript First-Strand Synthesis System (Invitrogen, Carlsbad, CA). PCR reactions were carried out using 50 ng of total parathyroid RNA under the following conditions: 95°C for 2 minutes, 40 cycles of 95°C for 15 seconds, and 60°C for 30 seconds. A real-time PCR reaction mixture was 25 μl (12.5 μl TaqMan Mix, 0.5 μl cDNA, 0.6 μl forward primer, 0.6 μl reverse primer, 0.3 μl probe, and 10.5 μl water). Primers and TaqMan probes for each target are listed in Table 2. Values were normalized to glyceraldehyde-3-phosphate dehydrogenase mRNA levels in each sample as measurement by each investigator.
