ABSTRACT

Background Early reports indicate that AKI is common among patients with coronavirus disease 2019 (COVID-19) and associated with worse outcomes. However, AKI among hospitalized patients with COVID-19 in the United States is not well described.

Methods This retrospective, observational study involved a review of data from electronic health records of patients aged ≥18 years with laboratory-confirmed COVID-19 admitted to the Mount Sinai Health System from February 27 to May 30, 2020. We describe the frequency of AKI and dialysis requirement, AKI recovery, and adjusted odds ratios (aORs) with mortality.

Results Of 3993 hospitalized patients with COVID-19, AKI occurred in 1835 (46%) patients; 347 (19%) of the patients with AKI required dialysis. The proportions with stages 1, 2, or 3 AKI were 39%, 19%, and 42%, respectively. A total of 976 (24%) patients were admitted to intensive care, and 745 (76%) experienced AKI. Of the 435 patients with AKI and urine studies, 84% had proteinuria, 81% had hematuria, and 60% had leukocyturia. Independent predictors of severe AKI were CKD, men, and higher serum potassium at admission. In-hospital mortality was 50% among patients with AKI versus 8% among those without AKI (aOR, 9.2; 95% confidence interval, 7.5 to 11.3). Of survivors with AKI who were discharged, 35% had not recovered to baseline kidney function by the time of discharge. An additional 28 of 77 (36%) patients who had not recovered kidney function at discharge did so on posthospital follow-up.

Conclusions AKI is common among patients hospitalized with COVID-19 and is associated with high mortality. Of all patients with AKI, only 30% survived with recovery of kidney function by the time of discharge.

JASN 32: 151–160, 2021. doi: https://doi.org/10.1681/ASN.2020050615
Small studies from China, Europe, and the United States thus far have reported a wide range of the incidence of AKI, ranging between 1% and 42%. The two largest studies published to date show widely disparate rates of AKI. Guan et al.\(^2\) reported an incidence rate of AKI of only 0.5% in 1099 patients from 552 hospitals in China. In a study out of Ireland, in patients admitted to the intensive care unit (ICU), reported incidence of AKI requiring dialysis was 22.2%, with mortality exceeding 75%.\(^3\) In New York, 37% of patients developed AKI, and 14% of patients with AKI required dialysis.\(^4\)

New York City (NYC) has been at the epicenter of the COVID-19 pandemic in the United States and worldwide and as such, has had the highest number of hospitalizations. The burden of severe AKI in the setting of COVID-19 has led to widespread shortages in NYC of dialysis nurses, machines, replacement fluids and cartridges for continuous RRT, and dialysis.\(^4,5\) The number of patients with AKI requiring acute RRT is unprecedented in modern history.

Despite the anecdotal stories regarding the incidence and severity of AKI, the epidemiology of AKI, especially recovery from AKI in hospitalized patients in the United States and particularly NYC, is not well described. Thus, the objective of this report was to describe the incidence, severity, risk factors, and outcomes associated with AKI in the setting of hospitalization of COVID-19 in a major NYC health care system.

METHODS

Study Population
The Mount Sinai Health System (MSHS) serves a large racially and ethnically diverse patient population. In this study, patient data came from the electronic health records (EHRs) from five major hospitals that are part of MSHS: Mount Sinai Hospital located in East Harlem, Manhattan; Mount Sinai Morningside located in Morningside Heights, Manhattan; Mount Sinai West located in Midtown and the West Side, Manhattan; Mount Sinai Brooklyn located in Midwood, Brooklyn; and Mount Sinai Queens located in Astoria, Queens. Mount Sinai Beth Israel was not included in this cohort as they used a different EHR.

Inclusion Criteria
We included patients who were at least 18 years old, had a laboratory-confirmed SARS-CoV-2 infection, and were admitted to any of the aforementioned five MSHS hospitals between February 27 and 12 AM on May 30, 2020, with follow-up data until June 5, 2020 (time of data freeze). A confirmed case of COVID-19 was defined by a positive RT-PCR assay of a specimen collected via nasopharyngeal swab. The Mount Sinai Institutional Review Board approved this research under a broad regulatory protocol allowing for analysis of patient-level data.

Exclusion Criteria
We excluded patients with known ESKD prior to admission and patients who were hospitalized for <48 hours (Supplemental Figure 1, Supplemental Table 1).

Data Collection
The dataset was obtained from different sources and aggregated by the Mount Sinai COVID Informatics Center (MSCIC; further description of MSCIC is provided in Supplemental Material). We obtained demographics, diagnosis codes (International Classification of Diseases 9/10 Clinical Modification [ICD-9/10-CM] codes), and procedures as well as vital signs and laboratory measurements during hospitalization. Demographics included age, sex, and language as well as race and ethnicity in the EHR. Racial groups included White, Black, Asian or Pacific Islander, and other. Ethnic groups included non-Hispanic/Latino, Hispanic/Latino, or unknown. Vital signs and laboratory values during the first 48 hours of admissions that were obtained as part of clinical care were included.

Definitions of Preexisting Conditions
We defined a preexisting condition as the presence of ICD-9/10-CM codes associated with specific diseases as per the Elixhauser Comorbidity Software.\(^6,7\)

Definitions of Outcomes
AKI, the primary end point, was defined as per Kidney Disease Improving Global Outcomes (KDIGO) criteria: a change in the serum creatinine of 0.3 mg/dl over a 48-hour period or 50% increase in baseline creatinine.\(^8\) For patients with a previous serum creatinine in the 7–365 days prior to admission, the most recent serum creatinine value was considered the baseline creatinine. For patients without a baseline creatinine in the 7–365 days prior to admission, the admission creatinine was imputed on the basis of a Modification of Diet in Renal Disease (MDRD) eGFR of 75 ml/min per 1.73 m as per the KDIGO AKI guidelines.\(^8\) AKI stages were defined using the KDIGO AKI stage creatinine definitions: stage 1 as an increase in serum creatinine of ≥0.3 mg/dl or increase to ≥1.5–1.9 times baseline serum creatinine, stage 2 as an
Statistical Analyses
Baseline characteristics were reported as medians and interquartile ranges (IQRs) for continuous variables. Categorical variables were summarized as counts and percentages. We used Kruskal–Wallis for continuous variables and chi-squared tests for comparison across groups. For survival analyses, we generated Kaplan–Meier survival curves, and comparison was done using the log-rank test. Patients who were discharged from the hospital were not censored and were still considered at risk for death. Patients who were still hospitalized at the time of data freeze were regarded as having a censored length of stay. Logistic regression models adjusted for covariates (adjusted for age; sex; race; comorbidities including CKD, hypertension, congestive heart failure, diabetes mellitus, liver disease, and peripheral vascular disease; laboratory values including white blood cell count, lymphocyte percentage, hemoglobin, platelets, sodium, potassium, aspartate aminotransferase, alkaline phosphatase, and albumin; and vitals including temperature, systolic BP, heart rate, respiratory rate, and oxygen saturation) were used to estimate the adjusted odds ratio (aOR) for death in patients with AKI versus without AKI. Covariates were chosen on the basis of univariate testing and physician input. We used local regression (loess) for smoothening creatinine values across the interval of 2 weeks posthospital admission to visualize trajectories by AKD category. All analyses were performed with R version 3.4.3 and SAS 9.4 (SAS Institute Inc., Cary, NC).

RESULTS
A consort diagram of included patients and outcomes is depicted in Supplemental Figure 1.

Demographic and Clinical Characteristics
From February 27 to May 30, 2020, 3993 COVID-19–positive patients who fulfilled our inclusion and exclusion criteria were hospitalized at one of five MSHS NYC hospitals. One hundred twenty-four (3%) of patients were still admitted at the time of manuscript drafting. Ninety-two percent of patients had a positive SARS-CoV-2 PCR test on the day of admission. Baseline creatinine was available prior to admission in 1455 (36%); for the patients without baseline creatinine, this was imputed using the MDRD equation as described in Methods. Patient demographics and preexisting conditions as well as vital signs and laboratory values stratified by AKI are displayed in Table 1. Patients who developed incident AKI were older and were more likely to have hypertension, congestive heart failure, diabetes mellitus, and CKD. Patients who developed AKI also had higher white blood cell count, lower lymphocyte percentages, and higher creatinine values. Other variables were statistically significant but likely not clinically significant given small absolute differences.

Incidence and Severity of AKI
AKI occurred in 1835 patients (46%), and 347 (19%) of those with AKI required dialysis. In the 976 (24%) patients admitted to intensive care, 745 (76%) experienced AKI. The median time from hospital admission until AKI diagnoses was 1 (IQR, 1–4) day, and the median time from AKI diagnosis to dialysis need was 3 (IQR, 1–6) days. The proportions of patients with AKI in all patients and in the ICU varied by the five MSHS locations (Table 1, Supplemental Table 3). In all admissions, the proportions with stages 1, 2, and 3 AKI were 39%, 19%, and 42%, respectively. In those admitted to the ICU, the proportions were 28%, 17%, and 56%, respectively, and 32% required acute RRT (Figure 1). The median peak serum creatinine was 2.2 (IQR, 1.5–3.6) mg/dl in those who did not receive dialysis and was 8.2 (IQR, 6.1–11) mg/dl in those who did receive dialysis. The proportions of AKI and of AKI stages were not different when limited to only those with a prehospital baseline creatinine or when the nadir hospital creatinine was used as the baseline (data not shown).

AKI incidence in patients who had a baseline creatinine was 49%, while in patients who had imputed baseline creatinine it was 45%, P=0.02. Urine studies were available for 656 (16%) patients, of whom 435 (66%) patients had AKI; 639 (97%) of all patients had any urinary abnormalities. Of the 435 patients with AKI and urine studies, 84% had proteinuria, 81% had hematuria, and 60% had leukocyturia. Proteinuria, hematuria, and leukocyturia were significantly more common in patients with AKI than patients without AKI (Supplemental Figure 2).

AKI Recovery
Among 1835 patients with AKI, 832 were discharged from the hospital. At hospital discharge, 541 of 832 (65%) had recovery of AKI, and 291 (35%) had AKD; the median serum creatinine

AST, aspartate transaminase; ALT, alanine transaminase; BPM, beats per minute.

at discharge was 1.1 (IQR, 0.8–1.6 mg/dl) (Figure 2). Only 30% (541 of 1835) of patients with AKI recovered kidney function and were discharged alive; 212 of 1835 (12%) patients who had AKI during their hospitalization had posthospitalization follow-up creatinine data at a median of 21 (IQR, 8–38) days after hospital discharge (Figure 2). On follow-up, of the 77 of 212 (36%) patients with AKD on discharge, 28 of 77 (36%) had recovery of AKD on follow-up. Of the 135 of 212 (64%) patients who had recovery of AKI at discharge, 18 of 135 (14%) had AKD on follow-up (Figure 2). Of the 87 of 832 patients who started on dialysis and were discharged alive, 26 (30%) patients required dialysis within 72 hours of discharge. At 7 days after AKI diagnoses or at discharge or death if it occurred before 7 days, 720 of 1835 (39%) had AKI recovery. The characteristics of patients by recovery and each AKD stage are presented in Supplemental Table 4. Creatinine trends by recovery group are presented in Figure 3 for differing subsets of the population.
Independent Predictors of Severe AKI

Independent predictors of incident stage 3 AKI in patients \((n=731)\) admitted to the hospital with COVID-19 were men \((\text{aOR}, 1.46; 95\% \text{ confidence interval [95\% CI]}, 1.2 \text{ to } 1.8)\), admission potassium \((\text{aOR}, 1.7; 95\% \text{ CI}, 1.6 \text{ to } 2.0)\), and CKD \((\text{aOR}, 2.8; 95\% \text{ CI}, 2.1 \text{ to } 3.7)\) (Supplemental Figure 3).

AKI and Outcomes

Patients with AKI were more likely to have ICU admissions, have mechanical ventilation, and require vasopressors administration (Supplemental Table 5). In-hospital mortality in patients who experienced AKI was 50%, and it was 8% in patients without AKI \((P<0.001)\). In-hospital mortality percentages of patients with AKI in the ICU (42%), and non-ICU setting (62%) were markedly higher than those without AKI (ICU, 7% and non-ICU, 13%). The results of Kaplan–Meier survival analysis stratified by AKI status are presented in Figure 4. Patients with AKI had significantly lower survival than patients without AKI (log-rank \(P\) value <0.001). After adjustment for demographics, comorbidities, and laboratory values, the aOR for death was 11.4 (95% CI, 7.2 to 18) for ICU with AKI versus no AKI, and the aOR for death was 9.2 (95% CI, 7.5 to 11.3) for all patients with AKI versus no AKI (Supplemental Table 6). There was an increasing risk of death with increasing stages of AKI, with the highest risk seen in patients with AKI stage 3 requiring dialysis (Supplemental Table 6).

DISCUSSION

In nearly 4000 patients with COVID-19 admitted to MSHS, AKI occurred in nearly half of patients, and nearly a quarter of those patients required acute dialysis. AKI was independently associated with higher mortality. Many survivors (35%) did not recover kidney function by hospital discharge, and of all patients with AKI, only 30% survived and recovered kidney function.

Although the current COVID-19 pandemic is caused by a coronavirus like the severe acute respiratory syndrome coronavirus 1 outbreak in 2005, the reported incidence of AKI associated with COVID-19 disease seems to be substantially higher. Additionally, the incidence of AKI associated with COVID-19 is higher than reported in patients hospitalized with community-acquired pneumonia (34%) and severe sepsis (22%) in the United States. During the last pandemic in recent history, the 2009 pandemic influenza A (H1N1), AKI incidence was found to be high (34%–67%). Although the incidence of AKI may be similarly high between the two pandemics, the spread of COVID-19 far exceeds than that of the H1N1 pandemic: 2 million people with confirmed COVID-19 in the United States over the first 6 months compared with 1 million with confirmed H1N1 over a 10-year period. Reports suggest that rhabdomyolysis may have been a contributing factor to AKI from H1N1. Although we do not have creatinine kinase values, the presence of proteinuria, leukocyturia, and hematuria in patients with COVID-19–associated AKI suggests a different mechanism of injury.

The incidence of AKI in this study is higher than what has been reported in China and Italy and similar to the incidence in another NYC health care system. There are several key differences in the MSHS cohort, including higher proportions of patients with comorbidities of hypertension, diabetes, and CKD, which are risk factors for developing AKI.
Figure 2. Approximately a third of patients did not have renal recovery at discharge or post-hospitalization follow up. Proportion of patients with AKI stratified by recovery versus nonrecovery at discharge and discharge follow-up. Recovery of kidney function was stratified into recover and AKD defined as (1) recovery: difference in creatinine is ≤0.3 and creatinine change in percentage is ≤25%; (2) stage 1: difference in creatinine is >0.3 and creatinine change in percentage is ≤25% or creatinine change in percentage is >25% and ≤100%; (3) stage 2: creatinine change in percentage is >100% and ≤200%; and (4) stage 3: creatinine change in percentage is >200% or requiring dialysis 72 hours prior to discharge.
analysis, there was no association between hypertension and diabetes with severe AKI, but CKD was independently associated with severe AKI. As others have reported, patients who were admitted to the ICU had a higher incidence of AKI likely reflective of more severe disease.

Currently, the exact mechanisms of AKI due to COVID-19 are unclear. A postmortem patient series reported by Su et al. found significant acute tubular injury in all patients. A separate study found a high frequency of urinalysis abnormalities (hematuria, proteinuria, and leukocyturia) despite normal creatinine values; which suggest renal pathology is not limited to acute tubular injury (Zhou H, Zhang Z, Fan H, Li J, Li M, Dong Y, et al. Urinalysis, but not blood biochemistry, detects the early renal-impairment in patients with COVID-19. https://www.medrxiv.org/content/10.1101/2020.04.03.20051722v1.full.pdf, 2020). In this study, of patients who had urine studies sent, nearly all patients had urine abnormalities. Although urine abnormalities were more frequent in patients with AKI diagnosis, a large proportion of patients without AKI by creatinine criteria also had urine abnormalities. These findings are in contrast to studies in critically ill patients and patients undergoing cardiac surgery that demonstrated that only 33%–48% of patients had proteinuria and that 65% had hematuria. Given the high incidence of AKI and lack of full recovery at and after discharge, identification of potential mechanisms of COVID-19–related AKI would allow for potential interventions to reduce this devastating complication.

This study is the first study in the United States to report the persistence of kidney dysfunction (lack of recovery) in survivors of COVID-19–associated AKI. A third of patients with AKI in the setting of COVID-19 did not recover kidney function back to baseline. The low recovery rate is expected given the overall severity of AKI (high peak creatinine, need for dialysis), as well as the knowledge that many patients with COVID-19 have extensive acute tubular injury on tissue examination, potential microthrombi, and a high prevalence of proteinuria. A study in a Chinese cohort reports similar findings, with less than half of patients fully recovering kidney function. This is in marked contrast to other forms of AKI where over 80% of patients recover their renal function by 10 days. It remains to be seen what the implications for post-AKI CKD, progression of prior CKD, and ESKD are for COVID-19–associated AKI. This will require long-term follow-up and further investigation.
Our study should be interpreted in light of the following limitations. Over half of patients did not have a baseline creatinine values. However, we used MDRD imputation as suggested by KDIGO guidelines, and the incidence was comparable for those with known baseline serum creatinine versus those who we imputed because of missing serum creatinine prior to admission.8 Although we presented data stratified by those who did and did not have ICU admissions, we did not examine the temporal relationship between the development of AKI and ICU admission. We did not have data regarding acute respiratory distress syndrome or ICU severity scores (e.g., Acute Physiology and Chronic Health Evaluation or Sequential Organ Failure Assessment), which are often associated with AKI and need for dialysis. However, many features that make up these scores (age, vital signs, and laboratory values) were features that we included in our multivariable model. Recovery was assessed at time of discharge, and we only had postdischarge creatinine values in a subset of patients. As patients could receive dialysis care outside of the MSHS, we are unable to determine dialysis dependence at postdischarge follow-up. As the COVID-19 pandemic is still evolving, few long term follow-up laboratory test have been performed. We did not have sufficient data on inflammatory makers (e.g., IL-6, ferritin, and fibrinogen) in a large proportion of patients because they were not routinely checked early in the pandemic and a majority of patients did not have these values (Paranjpe I, Russak A, Freitas JKD, Lala A, Miotto R, Vaid A, et al.; Mount Sinai Covid Informatics Center [MSCIC]; Clinical characteristics of hospitalized Covid-19 patients in New York City. medRxiv:2020.04.19.20062117, 2020). Additionally, urinalysis was also missing in the majority of patients. Although we provide analysis of the subset of patients who did have urine studies obtained, this is likely a bias subset as the urine samples were obtained for a clinical reason. Lastly, baseline medications of interest, including angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, statins, and other nonsteroidal anti-inflammatory drugs, were not included. In conclusion, in a diverse cohort of patients hospitalized with COVID-19 in NYC, we described a very high incidence of AKI, severe AKI requiring dialysis, and risk of death associated with AKI. We identified several predictors associated severe AKI and found that a third of patients did not recover kidney function at time of discharge. The results of this study may be useful to other centers for resource planning during the COVID-19 pandemic, for potential additional waves of COVID-19, and for preparing for the increased load of patients with COVID-19 and CKD due to severe AKI and lack of recovery.

**DISCLOSURES**

S. Coca, J.C. He, B. Murphy, and G. Nadkarni receive financial compensation as consultants and advisory board members for RenalytixAI and own equity in RenalytixAI. Z. Fayad has a patent Trained Therapeutix discovery patents with royalties paid to Trained Therapeutix Discovery. B. Murphy is a nonexecutive director of RenalytixAI. B. Murphy reports personal fees from Renalytix AI, outside the submitted work. All remaining authors have nothing to disclose.
FUNDING

None.

ACKNOWLEDGMENTS

To all of the nurses, physicians, and providers who contributed to the care of these patients. To the patients and their family members who were affected by this pandemic.

Dr. Lili Chan, Dr. Steven Coca, and Dr. Girish Nadkarni conceptualized and designed the study; Dr. Lili Chan, Dr. Kumandeep Chaudhary, Dr. Steven Coca, and Dr. Girish Nadkarni provided acquisition, analysis, or interpretation of data; Dr. Lili Chan, Dr. Kumandeep Chaudhary, Dr. Steven Coca, Dr. Girish Nadkarni, and members of MSCIC had full access to all of the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis; Dr. Lili Chan, Dr. Steven Coca, and Dr. Girish Nadkarni drafted the manuscript; Dr. Kumandeep Chaudhary, Dr. Kinsuk Chauhan, Dr. Aparna Saha, and Dr. Akhil Vaid provided statistical analysis; members of MSCIC provided administrative, technical, or material support; Dr. Steven Coca and Dr. Girish Nadkarni provided supervision; and all authors critically revised the manuscript for important intellectual content.

Dr. Lili Chan reports grants from the National Institutes of Health and Renal Research Institute, outside the submitted work. In the past 3 years, Dr. Steven Coca has received consulting fees from Bayer, Boehringer-Ingelheim, CHF Solutions, Goldfinch Bio, inRegen, pixelData, Quark, Relypsa, and Takeda Pharmaceuticals, and National Institutes of Health grants U01DK106962, R01DK115562, R01HL1085757, U01OH113266, R01DK112238, and RRTI UG 2019 outside the submitted work. Dr. Zahi Farjad reports grants from Amgen, Bristol Myers Squibb, Daichi Sankyo, and Siemens Healthineers and personal fees from Alexion, GlaxoSmithKline, and Trained Therapeutix Discovery, outside the submitted work. Dr. John C. He reports fees from RenalytixAL and grants from Alexion, GlaxoSmithKline, and Trained Therapeutix Discovery, outside the submitted work.

Title: Acute Kidney Injury in Hospitalized Patients with COVID-19

Supplemental Methods:

Mount Sinai COVID Informatics Center (MSCIC) Data Platform

This dataset of clinical data is the first part of a larger effort that aims to create an heterogeneous collection of COVID-19 patient data. This effort brings together different stakeholders from MSHS, including research faculty, data scientists, clinicians, and hospital administrators, among others. The resulting dataset includes or will include longitudinal electronic health record (EHR) patient clinical data, multi-omics, such as genomics, imaging, such as chest CT scans, among others. The data, which are updated on a daily basis, is made available within a secure computational framework based on internal Microsoft Azure Cloud to researchers and analysts within the MSHS and the Icahn School of Medicine at Mount Sinai. This dataset is intended to foster research projects to improve the knowledge of this disease and augment clinical operations with machine intelligence.

Hasso Plattner Institute for Digital Health at Mount Sinai

Laura Huckins, PhD
Assistant Professor
Genetic and Genomic Sciences

Paul O'Reilly, PhD
Senior Faculty
Genetics and Genomic Sciences

Riccardo Miotto, PhD
Assistant Professor
Hasso Plattner Institute for Digital Health at Mount Sinai

Zahi Fayad, PhD
Institute Director
BioMedical Engineering & Imaging Institute (BMEII)
Data Scientists/Analysts

Adam J. Russak, MD
Resident
Internal Medicine

Adeeb Rahman, PhD
Associate Professor
Genetics and Genomic Sciences

Akhil Vaid
Postdoctoral Fellow
Genetics and Genomic Sciences

Amanda Le Dobbyn, PhD
Research Assistant Professor
Genetics and Genomic Sciences

Andrew Leader
MD/PhD Student
Oncological Sciences

Arden Moscati
Statistical Geneticist
Charles Bronfman Institute for Personalized Medicine

Arjun Kapoor
Medical Student
Hasso Plattner Institute for Digital Health at Mount Sinai

Christie Chang
Data Science Analyst I
Immunobiology

Christopher Bellaire
Medical Student
Icahn School of Medicine at Mount Sinai

Daniel Carrion, PhD, MPH
Postdoctoral Fellow
Environmental Medicine and Public Health

Fayzan Chaudhry
Data Analyst
Genetics and Genomic Sciences

Felix Richter
MD/PhD Student
Graduate School of Biomedical Sciences

Georgios Soultanidis, PhD
Postdoctoral fellow
BioMedical Engineering and Imaging Institute

Ishan Paranjpe
Medical Student
Hasso Plattner Institute for Digital Health at Mount Sinai

Ismail Nabeel, MD, MPH
Associate Professor
Environmental Medicine and Public Health

Jessica De Freitas
PhD Student
Hasso Plattner Institute for Digital Health at Mount Sinai

Jiayi Xu
Postdoctoral Fellow
Pamela Sklar Division of Psychiatric Genomics

Johnathan Rush
Biostatistician
Environmental Medicine and Public Health

Kipp Johnson, PhD
MD/PhD student (completed PhD)
Genetics and Genomic Sciences

Krishna Vemuri, MPH
Biostatistician I
Environmental Medicine & Public Health

Kumardeep Chaudhary, PhD
Postdoctoral Fellow
Charles Bronfman Institute for Personalized Medicine

Lauren Lepow
Neuroscience Graduate Student and PGY-3 Psychiatry Resident
Psychiatry

Liam Cotter
Master’s Student
Psychiatric Genomics / Hasso Plattner Institute for Digital Health at Mount Sinai

Lora Liharska, MS
PhD student
Genetics and Genomic Sciences

Marco Pereanez
Programmer Analyst
BioMedical Engineering & Imaging Institute (BMEII)

Mesude Bicak, PhD
Senior Scientist
Genetics and Genomics Department

Nicholas DeFelice, PhD
Assistant Professor
Environmental Medicine & Public Health

Nidhi Naik
Masters’ student
Icahn School of Medicine at Mount Sinai

Noam Beckmann
Postdoctoral Fellow
Genetic and Genomic Sciences

Rajiv Nadukuru, MS
Database Analyst III
Personalized Medicine Institute

Ross O’Hagan
Medical Student
Hasso Plattner Institute for Digital Health at Mount Sinai

Shan Zhao
Resident
Anesthesiology, Perioperative & Pain Medicine

Sulaiman Somani
Medical Student
Icahn School of Medicine at Mount Sinai

Tielman T Van Vleck, PhD
Director of Clinical Linguistics and Data Science, BioMe Phenomics Center
Institute for Personalized Medicine

Tinaye Mutetwa
Research Trainee
General Internal Medicine

Tingyi Wanyan
Visiting Research Associate
Genetics and Genomic Sciences

Valentin Fauveau
Programmer Analyst II
BioMedical Engineering & Imaging Institute (BMEII)

Yang Yang, PhD
Assistant Professor
Radiology

Yonit Lavin
Resident
Internal Medicine
Operations/Infrastructure

AlonaLanksy
Clinical Research Coordinator
Oncological Sciences

Ashish Atreja, MD, MPH
Associate Professor
Gastroenterology
Pathology, Molecular and Cell Based Medicine

Diane Del Valle
Project Manager
Immunobiology

Dara Meyer, MS, PMP
Senior Project Manager
Genetics and Genomic Sciences

Eddy Golden, MPH
Program Manager
Hasso Plattner Institute for Digital Health at Mount Sinai

Farah Fasihuddin
Clinical Research Coordinator II
Gastroenterology

Huei Hsun Wen
Clinical Research Coordinator
Hasso Plattner Institute for Digital Health at Mount Sinai

Jason Rogers
Program Manager
Mount Sinai AppLab

Jennifer Lilly Gutierrez, MS
Communications Director
Genetics and Genomic Sciences
Icahn Institute for Data Science and Genomic Technology

Laura Walker
Clinical Research & Project Manager, Lead of CITE-seq team
Human Immune Monitoring Center (HIMC)

Manbir Singh
Associate IT Director
Hasso Plattner Institute for Digital Health at Mount Sinai

Matteo Danielello, PhD
Postdoctoral Fellow
Hasso Plattner Institute for Digital Health at Mount Sinai

Melissa A. Nieves, BA
Grants Manager
Hasso Plattner Institute for Digital Health at Mount Sinai

Micol Zweig, MPH
Associate Director
Hasso Plattner Institute for Digital Health at Mount Sinai

Renata Pyzik, MS, MA
Project Manager
Radiology / BioMedical Engineering & Imaging Institute (BMEII)

Rima Fayad, MPH
Clinical Research Manager
Radiology

Patricia Glowe
Sr. Director, Strategy & Operations
Hasso Plattner Institute for Digital Health at Mount Sinai

Sharlene Calorossi
Program Manager II
Genetics and Genomic Sciences

Sparshdeep Kaur
Clinical Research Manager
Hasso Plattner Institute for Digital Health at Mount Sinai

Kristin Meliambro, MD
Assistant Professor
Medicine, Nephrology

Madhav C. Menon, MD
Associate Professor
Medicine, Nephrology

Joshua L. Rein, DO
Instructor
Medicine, Nephrology

Shuchita Sharma, MD
Assistant Professor
Medicine, Nephrology

Joji Tokita, MD
Associate Professor
Medicine, Nephrology

Jaime Uribarri, MD
Professor
Medicine, Nephrology

Joseph A. Vassalotti, MD
Professor
Medicine, Nephrology

Jonathan Winston, MD
Professor
Medicine, Nephrology

Kusum S. Mathews, MD, MPH, MSCR
Assistant Professor
Medicine, Pulmonary, Critical Care and Sleep
Emergency Medicine
Leadership Oversight Board

**Dennis Charney, MD**  
Dean, Icahn School of Medicine at Mount Sinai  
President for Academic Affairs, Mount Sinai Health System  
Professor, Psychiatry  
Professor, Neuroscience  
Professor, Pharmacological Sciences

**Eric Nestler, MD, PhD**  
Dean for Academic Science Affairs  
Director, Friedman Brain Institute  
Professor, Neuroscience  
Professor, Pharmacological Sciences  
Professor, Psychiatry

**Barbara Murphy, MD**  
Dean, Clinical Integration and Population Health  
Chair of the Department of Medicine, Mount Sinai Health System  
Murray M. Rosenberg Professor of Medicine

**David Reich, MD**  
President & Chief Operating Officer  
The Mount Sinai Hospital and Mount Sinai Queens

**Erwin Bottinger, MD**  
Director, Hasso Plattner Institute for Digital Health at Mount Sinai  
Professor, Medicine and Systems Pharmacology and Therapeutics, Icahn School of Medicine at Mount Sinai, New York City, U.S.A.  
Director, Digital Health Center, Hasso Plattner Institute,  
Professor, Digital Health- Personalized Medicine, Hasso Plattner Institute and Universität Potsdam, Germany

**Kumar Chatani, MBA**  
Executive Vice President  
Chief Information Officer  
Dean for Information Technology  
Mount Sinai Health System

**Glenn Martin, MD**  
Senior Associate Dean for Human Subjects Research  
Associate Professor, Psychiatry  
The Mount Sinai Hospital

Scientific Advisory Board

**Eric Nestler, MD, PhD**  
Dean for Academic Science Affairs  
Director, Friedman Brain Institute  
Professor, Neuroscience  
Professor, Pharmacological Sciences  
Professor, Psychiatry

**Patricia Kovatch, BS**  
Senior Associate Dean for Scientific Computing and Data Science  
Associate Professor, Genetics and Genomic Sciences  
Associate Professor, Pharmacological Sciences

**Joseph Finkelstein, MD, PhD**  
Chief Research Informatics Officer  
Senior Associate Dean, Information Technology  
Professor, Population Health and Science  
Director, Center for Biomedical and Population Health informatics  
Associate Director, Cancer Information Technology at The Tisch Cancer Institute

**Barbara Murphy, MD**  
Dean, Clinical Integration and Population Health  
Chair of the Department of Medicine, Mount Sinai Health System  
Murray M. Rosenberg Professor of Medicine

**Joseph Buxbaum, PhD**  
Professor, Psychiatry  
Professor, Neuroscience  
Professor, Genetics and Genomic Sciences
Judy Cho, MD  
Dean of Translational Genetics  
Director, The Charles Bronfman Institute for Personalized Medicine  
Professor, Genetics and Genomic Sciences  
Professor, Medicine, Gastroenterology

Andrew Kasarskis, PhD  
Executive Vice President  
Chief Data Officer, Mount Sinai Health System  
Professor, Genetics and Genomic Sciences

Carol Horowitz, MD, MPH  
Dean for Gender Equity in Science and Medicine  
Professor, Population Health Science and Policy  
Professor, Medicine, General Internal Medicine

Carlos Cordon-Cardo, MD, PhD  
Professor and System Chair, Pathology, Molecular and Cell Based Medicine  
Professor, Oncological Sciences  
Professor, Genetics and Genomic Sciences

Monica Sohn  
Senior Executive Director of Development  
Precision Medicine & Children’s Health  
Mount Sinai Health System

Glenn Martin, MD  
Senior Associate Dean for Human Subjects Research  
Associate Professor, Psychiatry  
The Mount Sinai Hospital

Adolfo Garcia-Sastre, PhD  
Director, Global Health and Emerging Pathogens Institute  
Professor, Microbiology  
Professor, Medicine, Infectious Diseases

Emilia Bagiella, PhD  
Professor, Population Health Science and Policy  
Icahn School of Medicine at Mount Sinai

Florian Krammer, PhD  
Professor, Microbiology  
Icahn School of Medicine at Mount Sinai

Judith Aberg, MD  
Professor, Medicine, Infectious Diseases  
Icahn School of Medicine at Mount Sinai

Jagat Narula, MD, PhD  
Associate Dean for Global Affairs  
Professor, Medicine, Cardiology  
Professor, Radiology

Robert Wright, MD, MPH  
Professor and System Chair, Environmental Medicine & Public Health  
Professor, Pediatrics  
Director, Institute for Exposomic Research

Erik Lium, PhD  
President, Mount Sinai Innovation Partners  
Executive Vice President and Chief Commercial Innovation Officer  
Mount Sinai Health System

Rosalind Wright, MD  
Dean for Translational Biomedical Research  
Professor, Pediatrics, Pulmonary and Critical Care  
Professor, Environmental Medicine & Public Health  
Professor, Medicine, Pulmonary, Critical Care and Sleep Medicine

Annette Gelijns, PhD, JD  
Professor and System Chair  
Population Health Science and Policy

Valentin Fuster, MD, PhD  
Director, Zena and Michael A. Wiener Cardiovascular Institute  
Physician-in-Chief, The Mount Sinai Hospital  
Professor, Medicine, Cardiology

Miriam Merad, MD, PhD  
Director, Precision Immunology Institute  
Professor, Oncological Sciences  
Professor, Medicine, Hematology, and Medical Oncology
